Asystent Nauczyciela - Dokumentacja

Julian Kominiak

1. Projekt interfejsu graficznego

Średnia: 3.93

2. Tworzenie bazy danych

Do stworzenia bazy danych wykorzystałem lokalną bazę danych room, która zainicjalizowana jest w następujący sposób:

```
@Database(entities = [Subject::class, Student::class, Class::class, Mark::class], version = 13,
    exportSchema = false)
abstract class TeacherAssistantDatabase : RoomDatabase() {
    abstract val dao: TeacherAssistantDAO
    companion object {
        @Volatile
        private var INSTANCE: TeacherAssistantDatabase? = null
        fun getInstance(context: Context): TeacherAssistantDatabase {
            synchronized(this) {
                var instance = INSTANCE
                if (instance == null) {
                    instance = Room.databaseBuilder(
                        context.applicationContext,
                        TeacherAssistantDatabase::class.java,
                        "teacher_assistant_database")
                         .fallbackToDestructiveMigration()
                         .allowMainThreadQueries()
                         .build()
                    INSTANCE = instance
                return instance
```

Następnie utworzyłem potrzebnę encje wraz z ich atrybutami:

```
@Entity(tableName = "subjects_table")
data class Subject(
     @PrimaryKey(autoGenerate = false)
     @ColumnInfo(name = "subject_name") var subjectName: String,
 @Entity(tableName = "marks_table")
data class Mark(
     @PrimaryKey(autoGenerate = true)
     @ColumnInfo(name = "id") var id: Long,
     @ColumnInfo(name = "value") var value: Float,
     @ColumnInfo(name = "parent_student_id") var parentStudentId: Long
 @Entity(tableName = "students_table")
 data class Student(
    @PrimaryKey(autoGenerate = true)
    @ColumnInfo(name = "id") var id: Long,
    @ColumnInfo(name = "parent_subject_name") var parentSubjectName: String,
     @ColumnInfo(name = "name") var name: String,
     @ColumnInfo(name = "surname") var surname: String
@Entity(tableName = "classes_table")
data class Class(
    @PrimaryKey(autoGenerate = true)
    @ColumnInfo(name = "id") var id: Long,
    @ColumnInfo(name = "parent_subject_name") var parentSubjectName: String,
    @ColumnInfo(name = "day_of_week") var dayOfWeek: String,
    @ColumnInfo(name = "start_time") var startTime: String,
    @ColumnInfo(name = "end_time") var endTime: String
```

3. Dodatkowa funkcjonalność - obliczanie średniej

Dodatkową funkcjonalnością jest automatyczne obliczanie średniej dla danej osoby z wybranego przedmiotu. Kod odpowiedzialny za tą funkcjonalność wygląda następująco:

View:

```
android:id="@+id/average_mark"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:text="TextView"
android:textAppearance="@style/TextAppearance.AppCompat.Display1"
app:layout_constraintBottom_toTopOf="@+id/button_marks_to_students"
app:layout_constraintEnd_toEndOf="parent"
app:layout_constraintStart_toStartOf="parent" />
```

```
viewModel.marks.observe(viewLifecycleOwner) {
    marksListAdapter.notifyDataSetChanged()
    view.findViewById<TextView>(R.id.average_mark).text = buildString {
        append("Średnia: ")
        append(viewModel.getAverage())
    }
}
```

ViewModel:

```
fun getAverage(): String {
   val count = dao.countAllMarks(arguments?.get("studentId") as Long)
   val sum = dao.sumAllMarks(arguments.get("studentId") as Long)
   return "%.2f".format(sum / count)
}
```

Model:
